\textbf{A B S T R A C T}

The purpose of this article is to analyze the effect of hotel innovations on firm value. Specifically, this study fills a research gap in the previous literature by examining this effect through market value and by distinguishing the potentially different impacts of distinct innovation types: product, process, organization and marketing. This research contributes to consolidating the empirical evidence of hotel innovation and performance by analyzing whether distinct types of innovation lead to different levels of results. The findings show that innovations are perceived to have a positive impact on the future sales of the company: in a four-day period (0,+3), there is an increase in stock exchange returns of 1.53%. In terms of innovation types, process and marketing innovations are found to have a higher positive effect on hotel market value than product and organization innovations; which is explained by potential cost differences among innovations.

1. Introduction

This article analyzes the effect of innovation on the firm value of hotels. Innovation is a critical element in today's tourism companies (Sundbo et al., 2007; Martínez-Ros and Orfila-Sintes, 2009). It certainly helps firms reach and keep higher competitiveness standards (Aldebert et al., 2011; Hjalager, 2002; Kumar et al., 2008; Pulido et al., 2011; Rodgers, 2007; Zach et al., 2010) as well as growth (Love et al., 2011). In the context of hotel management, Chen (2011) points out that “innovation appears to be the only means for an organization to convert change into opportunities and thus succeed”. In a recent article, Hjalager (2010) describes innovation research in tourism as a young phenomenon, suggesting several research gaps that should be tackled in order to get further insights that contribute to consolidating the theoretical underpinnings of tourism innovation. Specifically, this author, among others, points out a research gap in tourism innovation that should attract more analysis: the relationship between innovation actions and their economic performance. This author explicitly raises the question of examining “what types of innovation produce what level of results”. In an attempt to add to the extant body of knowledge on the topic, this article analyzes the effect of different types of innovations on the hotel industry's market value.

With this objective, the subsequent sections of the article are arranged as follows: Section 2 presents the literature review of innovation in the hotel industry and justifies the hypotheses; Section 3 outlines the methodology and data employed; Section 4 describes the results; and Section 5 presents the conclusions.

2. Innovation in the hotel industry

According to Hjalager (2010), the analysis of innovation in tourism helps us to understand its economic dynamics and, in this regard, several authors have studied different facets of hotel innovation: Jacob et al. (2010) examine environmental innovation as a competitive factor, Pulido et al. (2011) identify the critical external factors that influence innovation, González and León (2001) describe the determinant factors of environmental innovations, Hashim et al. (2010) explore the relationship between hotel characteristics and Internet adoption, Orfila-Sintes et al. (2005) show the characteristics that lead hotels to innovation, and Chang et al. (2011), Chen and Cheng (2012), Davidson et al. (2006) and Martínez-Ros and Orfila-Sintes (2012) analyze innovation through human resource management practices.

In general terms, four problems affect innovation management and its current practice (Van de Ven, 1986): the human problem of managing attention, the process problem of managing ideas into good currency, the structural problem of managing part–whole relationships, and the strategic problem of institutional leadership. Interestingly, these problems are still to be disentangled today; in a more recent publication, Van de Ven and Engleman (2004) still consider them to be core aspects in managing corporate entrepreneurship and innovation. These issues can be summed up as follows: (1) the human problem of managing attention. People are so focused on their daily activities in the company that
they do not pay great attention to the development of new ideas. The question here is that, unless there is leadership intervention, organizational members focus their attention on routine, rather than innovative activities. (2) The process problem of managing ideas into good currency. While conception of innovative ideas may be an individual activity, innovation (implementing new ideas) is a collective effort of pushing those ideas into good and wider acceptance. (3) The structural problem of managing part–whole relationships. Ideas can come from different areas of the firm, and multiple functions and resources are needed to transform an innovative idea into reality, so the question is how to put together all the “parts” to form a “whole”. (4) The strategic problem of institutional leadership. There is general agreement that institutional leadership is needed for organization innovation, particularly when a firm has to consider alternative ways of doing things.

Underlying all these issues is the relationship between innovation and performance: how can managers measure the effectiveness of the solutions to the above issues?

Innovation has been proven to be one of the most important determinants of organizational performance. Certainly, innovation activities are carried out to achieve, among others, production and marketing goals such as enhancement in product quality, production cost control, market share reinforcement, reaching new markets, production flexibility or improvement in management performance (Quadros et al., 2001; Walker et al., 2011), but innovative actions also foster an organizational learning climate with an enhancement-oriented approach with ongoing efforts aimed at reaching improvements, renewals and even learning from unsuccessful strategies (Gunday et al., 2011); note that the integration of technical and/or administrative changes into the organizational structure permits, first, adaptation to a competitive environment in which the only thing guaranteed is that “change is a constant” (Gunday et al., 2011), and second, improvement of the level of goal achievement (Damanpour and Evan, 1984). Not for nothing, Han et al. (1998) show that innovative activities lead to organizational growth and profitability, as they allow the firms to get synergies from the combination of technical and administrative innovations.

The central point is, therefore, how to measure the innovation–performance relationship. Critical decisions made by hotel managers, such as innovation investments, are obviously aimed at increasing the value of the company and, as a final objective, the creation of profits for investors. Consequently, a value-creating decision-maker must choose value-creating investments. When it comes to the analysis of the effect of innovation on tourism performance, research is limited (Hjalager, 2010).

The assessment of innovation on firm performance has been generally carried out through accounting measures, which rely on the figures that appear in the company’s balance sheet and income statement. Even though these measures provide a historical record of the past and present situation of the firm, they can be insufficient because (Myers, 1972): (i) they do not incorporate investor expectations of future profits; (ii) they could lead to confusion due to the deficiencies inherent in their dependence on different conventions (e.g., rate of depreciation), which make comparisons difficult; (iii) they do not reflect all the opportunity costs supported by the firm; and (iv) they do not allow the adjustment of differences in performance for differences in the risk supported by firms.

Alternatively, Orfila-Sintes and Mattsson (2009) – following Álvarez et al. (2001) – measure performance through the average occupancy rate and attempt to explain it by employing historical data on innovation (specifically, an aggregated measure of innovation over the last three years). These authors attempt to identify the determinant factors that lead hotels to choose from four different types of innovations (service scope, back-office, management, and external communication), and find that additional services on offer, booking made through tour operators, hotels being within a hotel chain and hotel ownership are explanatory factors of the types of innovation decisions. Additionally, they study the impact of innovation on performance. In this analysis, they test the effect of the aforementioned types of innovation on average hotel occupancy rate, finding that greater performance is achieved by hotels with a network of business relationships with both tour operators and chains, and whose ownership is in total control of outlays and new services (Orfila-Sintes and Mattsson, 2009). In general terms, they find, as expected, a positive impact of innovation on performance.

With a different approach, this article relies on market value. Market value has the advantage that it is based on growth prospects: assuming that shareholders behave rationally, share prices should reflect the present value of future cash flows and, therefore, it constitutes a good indicator to measure the impact of innovation activities on firm performance. Market value is defined as the product of the number of shares by the share price, which is considered to be the best unbiased estimate of the value of any investment. Market value analyses, such as the event study method, are founded, in the portfolio theory of financial economics, on the premises that stock markets are efficient and that a company’s share price reflects its strategy (e.g., innovation). In an efficient stock market, share prices reflect all the available information on a company. In fact any information received by the market (e.g., on innovation activities) will be instantly incorporated into the share price. Likewise, any change to a company’s share price will reflect, without bias, alterations to its future cash flows. Therefore, the introduction of new information on innovation allows an examination of share price behavior to explicitly analyze the underlying change to unbiased market predictions on future returns on the said innovation activity. This allows separation of returns derived from innovation activity by isolating them from the impact of other events. Accordingly, the use of market value facilitates the analysis of the effect of innovation on performance by estimating unbiased market predictions on future profits. As outlined later, market value is a forward-looking firm performance indicator that overcomes all the difficulties of the traditionally used backward-looking firm profitability (such as accounting measures).

Additionally, when measuring innovation effects, it is important to consider innovation variety. Martínez-Ros and Orfila-Sintes’ (2009) emphasize the strong heterogeneity and wide array of complex and highly innovative activities conducted in services. Certainly, the distinction of innovation types is not a straightforward task, especially because some of them might be intertwined, resulting in a more complex combination of effects (Hjalager, 2010; Oslo Manual, 2005). The two most used classifications by far are incremental vs. radical innovations (Dewar and Dutton, 1986), and the Schumpeterian taxonomy (Schumpeter, 1934; Oslo Manual, 2005). The former distinguishes between incremental and radical innovation in such a way that incremental entails “linear, cumulative change in a process or product, representing minor improvements or simple adjustments in current technology” while radical is “non-linear, paradigmatic changes, representing significant departures from existing practice or knowledge”. The latter encompasses product innovation, process innovation, organizational innovation and marketing innovation. According to Hjalager (2010), the Schumpeterian taxonomy has been more extensively used in tourism in order to look for innovation types and analyze their effects. For example, Hall’s (2009) study complies with the OECD’s four categories of innovation, in line with the Schumpeterian approach and Hjalager (1997) provides a basic categorization close to Schumpeter’s original (product innovations, classical process innovations, process innovations in information handling, management innovations, and institutional innovations). Hjalager (2010) also indicates that distribution innovations and institutional innovations are attempts to incorporate specificities of innovation in tourism. Following this trend, this article focuses on the OECD’s four categories,
which are described next and exemplified with cases obtained from the sample used:

Product Innovation is the “introduction of a good or service that is new or significantly improved with respect to its characteristics or intended uses. This includes significant improvements in technical specifications, components, materials, incorporated software, user-friendliness or other functional characteristics. Product innovations can utilize new knowledge or technologies, or can be based on new uses or combinations of existing knowledge or technologies” (Oslo Manual, 2005). Note that the notion “product” encompasses goods as well as services, and in either case, it implies a complex process influenced by technology development, shifts in customer needs and wants, length of product life cycles and degree of global competition (Gunday et al., 2011). As Akova et al. (1998) indicate, it implicitly leads to the observation of a strong interaction with all the decision making areas within the firm and the firm with its customers and suppliers. A product innovation involves the improvement of a product or service, which is critical for firms (Lenfle and Midler, 2009) and quintessential to their success (Malhotra et al., 1996), and is materialized in changes directly observed by the client and considered to be new (Hjalager, 2010). When NH Hotels set up the “plug & play” Internet system it was a novelty back at the turn of 2000 that added an extra service to the room itself; likewise, when this company installed the first “huhe bube restaurant” in their premises in 2003 it was a new concept widely acknowledged by their patrons (see Table 1). In the same vein, Sol Meliá has recently launched the Yhi Spa brand which again adds extra value to its core product. These are all new products/services in the shape of innovations that imply an investment but, at the same time, are expected to generate greater turnover.

Process innovation “is the implementation of a new or significantly improved production or delivery method. This includes significant changes in techniques, equipment and/or software. Process innovations can be intended to decrease unit costs of production or delivery, to increase quality, or to produce or deliver new or significantly improved products” (Oslo Manual, 2005). Note that, according to Gunday et al. (2011), process innovations are linked to technological developments. Here, special mention should be made of the role of ICT as a prevalent element in hotels’ process innovation, which is considered a critical investment in today’s tourism system. As before, all these innovations come with a cost that is expected to be subsequently paid-off. In fact, note that the emphasis on process innovation is on its cost-cutting nature (Fagerberg et al., 2004); that is, a basic objective of process innovation is to reduce costs irrespectively of the expected demand (e.g., Sol Meliá once announced that was going to take part in Endesa’s Energy Program to learn how to efficiently use energy in their hotels).

Organizational innovation “is the implementation of a new organizational method in the firm’s business practices, workplace organization or external relations. Organizational innovations can be intended to increase a firm’s performance by reducing administrative costs or transaction costs, improving workplace satisfaction (and thus labor productivity), gaining access to non-tradable assets (such as non-codified external knowledge) or reducing costs of supplies” (Oslo Manual, 2005). In other words, the introduction of new organizational methods within the firm to improve its operational practices, which are related with administrative efforts aimed at renewing the organizational routines, procedures, mechanisms or systems and promoting teamwork, information sharing, coordination, cooperation, collaboration, learning and innovativeness (Gunday et al., 2011). This type of innovation activity is not only important for the firm’s day-to-day operations but it is also especially relevant for tourism companies, which need to keep their best personnel from being lured away by competitors; or simply make their engagement with the company stronger (Ottenbacher and Gnoth, 2005; Hall and Williams, 2008). As examples, both NH and Sol Meliá have established variable monthly salaries for their staff depending on the share price or on the objectives accomplished.

Marketing innovation is “the implementation of a new marketing method involving significant changes in product design or packaging, product placement, product promotion or pricing. Marketing innovations are aimed at better addressing customer needs, opening up new markets, or newly positioning a firm’s product on the market, with the objective of increasing the firm’s sales” (Oslo Manual, 2005). It entails actions such as detecting new segments, redesigning promotional messages or introducing new alternative pricing methods (Ladany, 1996). A constant activity within this category is exemplified by loyalty programs (Hjalager, 2010). An example of this strategy is the “NH World” loyalty program, which allows the participant to not only enjoy specific advantages (e.g., express check-in) but to get personalized services as his/her preferences are known by the company. Certainly, loyalty programs are a consequence of the appearance of one-to-one marketing, which entails individual consideration of consumers and an individualized service. This approach is the basic pillar of relationship marketing and, therefore, the application of CRM (Customer Relationship Management), which is designed to create, strengthen and maintain relationships between companies and their customers, in order to maximize income per customer. Also, within this marketing innovation realm, the advent of the Internet had a huge impact on tourism intermediaries, not only because providers can now communicate with their customers directly but also because traditional wholesalers, such as Global Distribution Systems, can distribute their whole range to their potential clients with no intermediaries (e.g., Sabre sells to the final consumer through Travelt). The latter marketing innovation is so important that it has led tourism literature to consider “distribution innovations” as a separate category (Hjalager, 2010, p. 2). In fact, Daghsous and Barkhi (2009) indicate and Scaglione et al. (2009) prove that the role of new technologies in hotel services, operations and strategy is a critical component to reach a high level of both excellence and revenues. The relevance of distribution innovation favors its inclusion in any analysis of innovation types in the hotel industry, such as this article.

2.1. Hypotheses development

According to the previous literature review, two hypotheses are stated concerning the innovation–performance relationship.

Hypothesis 1. The development of the first hypothesis justifies the relationship. In general terms, there is agreement on the positive relationship between innovation and performance (Orfila-Sints and Mattsson, 2009), on account of the higher probability of survival (Hall and Williams, 2008), higher competitive edge gained (Victorino et al., 2005), the differentiation reached (Walsh et al., 2008) and cost reductions attained (Chan et al., 1998). As Quadros et al. (2001) and Walker et al. (2011) indicate, innovation allows companies to achieve improvement in different facets such as quality, costs, market share or production, among others: all of these advantages leading to improved organizational growth and profitability (Han et al., 1998). Therefore, according to the literature review in the previous section and the above research showing a positive relationship between innovation-related activities and performance, Hypothesis H.1 states that:

H.1. Innovation has a positive effect on hotel market value

Hypothesis 2. The second hypothesis considers innovation diversity and performance. Within the analysis of the effect of innovation on performance, Hjalager (2010) stresses the need to examine “what types of innovation produce what type of results”. At this point, it is important to emphasize the fact that not all innovations

3. Methodology

The methodology is built on the following two stages: first, estimation of abnormal returns, in which several sub-steps are followed; and second, detection of differences in innovation types.

Stage 1. The abnormal returns on a sample of innovations are estimated through an event study, which implies the identification of the date of the first announcement. Event studies base their formation on the idea that a particular event, such as an innovation announcement, affects the value of a firm; therefore, the objective is to observe the variation in hotel market value as a consequence of an innovation announcement on the day of the release.

Accordingly, an event-study method aims to estimate excess returns generated by a sample of unanticipated events – the basic hypothesis is that abnormal returns reflect stock market reaction to the arrival of new information; defining each event as an innovation announcement. The event study measures the impact of unanticipated events on share prices, based on the estimation of a market model for each company event and on the posterior calculation of abnormal returns. Specifically, the event study technique is based on the following data collection process (McWilliams and Siegel, 1997):

(i) The first step detects the innovation activities carried out by the only two hotel companies trading in the Spanish Stock Market between 1996 and 2008, Sol Meliá and NH Hotels. The Factiva database is used, which provides information on headlines and news items published in different newspapers of international and national coverage, as well as those of general and/or specialized content. To this end, a combination of key words is used, such as the “company name”, “innovation”, “innovate”, “novelty”, “new product”, “new service”, “new process”, “new procedure”, “new system” and “new technology” among others. The event day is defined as the first day in which the news is divulged in any of the publications used for the database. The search detects a sample of 24 innovations (see Table 1).

(ii) The second step uses a 11-day event window to test for any abnormal behavior in company share returns; i.e., the five days before and after (−5,+5) the announcement date. The reason for using an event window rather than just a single day is that, although it is expected that the majority of innovation information is quickly incorporated into share prices, it occasionally either leaks out before formal publication or is held back.

(iii) The third step looks for possible confounding news published in the event window, such as takeover bids, profit announcement, dividend declarations, split announcements, complaints, claims, government contracts, court cases, or labor disputes, etc. Fortunately, no such news items are found in the event window. Although this sample size could a priori seem somewhat small, the usual empirical applications of the event study technique show that it is large enough to detect reactions in share prices (see for example, Gómez (2001)). Also, it is important to stress the fact that the data collection process guarantees that these are all the news items released during the study period.

(iv) The fourth step estimates the market model after collecting data on market measures of performance, i.e., returns on the share price. Different frequencies (daily, weekly, monthly, annually, etc.) might lead to distinct measures, but the daily news collection procedure employed requires the use of daily returns. Market measures provide information on the value of the firm. Such data are not themselves free of problems, given that some markets may present inefficiencies or volatility on specific occasions (Ramírez and Espitia, 2001). But, they permit consideration of opportunity costs, risk supported by the firm, and capitalized value (expectations) of the profits of innovation activities, as well as minimizing the distortions resulting from tax laws and accounting standards.

The raw data are the daily returns on the shares of the two firms which made the 24 innovation announcements during the period July 2, 1996 to 31 December 31, 2008, a temporal period defined by the availability of daily stock market information. These daily returns are adjusted for dividends, subscription rights and splits. The returns on the share price of a company i on day t (Rit) are expressed as:

\[ R_{it} = \alpha_i + \beta_i R_{mt} + \epsilon_{it} \]  

where \( R_{mt} \) returns on the market portfolio on day t (this study uses the IBEX-35, a representative index of the Spanish Stock Market; the information is obtained from the Stock Exchange Society); \( \alpha_i \) = returns on the shares of company i independent of those of the market; \( \beta_i \) = sensitivity of returns on share i to variations in market returns; and \( \epsilon_{it} \) = error term that follows a autoregressive conditional heteroskedasticity model, GAR(1,1), so that \( \epsilon_{it} = h_{it}^{1/2} \eta_i \), where \( \eta_{it}^{1/2} \epsilon_{it} \) is identically and independently distributed with \( N(0, h_{it}) \); \( h_{it} \) is identically and independently distributed with \( E(h_{it}) = 0 \) and \( E(h_{it}^2) = 1 \), and \( h_{it} = \gamma_i + \lambda_i \epsilon_{it-1}^2 + \gamma_i h_{it-1} \), with \( \gamma_i \), \( \lambda_i \) and \( \gamma_i \) being parameters to be estimated. The estimation of Eq. (1) calculates daily abnormal returns (AR) for a company i announcement:

\[ AR_{it} = R_{it} - (\alpha_i + b_i R_{mt}) \]  

where \( a_i \) and \( b_i \) are the estimations of the regressions (1) for a period \( T \) before the event.

(v) The last step tests abnormal returns. To analyze the effect of a company’s innovation announcements on its share price, this article tests the significance of the average abnormal returns for its innovation announcements in the event window (−5,+5) using Brown and Warner’s (1980) and Jaffe’s (1974) tests.

Brown and Warner’s test is the basic test, and therefore, the starting point to potentially detect abnormal returns. This test is defined as

\[ t_1 = \frac{\sum_{i=1}^{N} AR_i}{\sqrt{\sum_{i=1}^{N} \sigma_{AR_i}^2}} \]

where \( N \) is the number of news releases, \( AR_i \) is the abnormal returns on the event date, and \( \sigma_{AR_i}^2 \) is the variance of share i obtained from the estimation period.

Jaffe’s (1974) test is also used in this analysis. The choice of this test is justified because of the potential presence of contemporary correlation problems in the sample selected, which may be derived, on the one hand, from the existence of overlapped periods for some of the news releases on different stocks and, on the other hand, from the fact that the companies included in the analysis belong to the same industry. Remember that, as the empirical analysis in this study is focused on the hotel sector, the firms used in the analysis belong to the same industry. These problems may well cause a biased estimate as Collins and Dent (1984) and Bernard (1987) have demonstrated, and can be avoided by using the Jaffe test, which is defined as:

\[ t_2 = \frac{\sum_{i=1}^{N} AR_i}{\sqrt{\sum_{i=1}^{N} \sigma_{AR_i}^2 + \sum_{i=1}^{N} \sum_{j=1}^{N} \frac{\sigma_{AR_i} \sigma_{AR_j}}{N}} \]  

where \( N \) is the number of news releases, \( AR_i \) is the abnormal returns on the event date, and \( \sigma_{AR_i}^2 \) is the variance of share i obtained from the estimation period.

Once the abnormal returns have been estimated and tested, a regression analysis is used to detect differences in the effects of each innovation type (product, process, organizational and marketing – together with distribution innovations).

4. Results

Table 2 shows the estimation of the average abnormal returns of the 24 announcements in several event windows. The results obtained demonstrate that, on average, innovation announcements are associated with positive excess returns on the post-event days; in particular, both tests – Brown and Warner, and Jaffe – present significant values in the window (+0,+3). This means that, on average, firms announcing innovation activities undergo a minimum gain of 1.53% on the days after the announcement. This delay seems plausible as innovation announcements can motivate investors to re-examine a company’s product positioning and strategy. It seems that they make a positive valuation of the innovations once they are re-evaluated and react accordingly. This result supports Hypothesis H.1 that innovation has a positive effect on a hotel’s market value, which is in line with the positive relationship between innovation and performance found by Hall and Williams (2008), Victorino et al. (2005), Walsh et al. (2008), Chan et al. (1998) and Orfla-Sintes and Mattsson (2009).

Once the abnormal returns are estimated and tested, the analysis of whether the distinct innovation types have differentiated effects on these abnormal returns is performed. Table 3 shows the results of the regressions conducted. Two equations are estimated: one with the traditional classification for innovations (product, process, organization and marketing) and another in which “distribution innovations” are extracted from “marketing innovations” so that they can be treated separately as a different category, in line with Hjalager (2010). Organization innovations are used as the base reference for the parameter estimation. Both equations have a global level of significance of 1%, their adjusted \( R^2 \) measures explain 41.7% and 44.9% respectively and the two equations show robust results: the significant parameters show consistent signs in both equations and their significance levels are the same.

As for the individual parameters, “process” and “marketing” innovations are found to be significantly greater than both “product/service innovations” and the reference category “organization innovations”. These greater returns are confirmed in the two equations. Also, chi-square tests find that there are no significant differences between “process” and “marketing” innovations in Eq. (1), and among “process”, “marketing” and “distribution” innovations in Eq. (2). These specific sizes of innovation impacts confirm Hypothesis H.2 that different innovation types undertaken by hotel companies have different effects on their market value; however, note that what is actually found is that “product/service innovations” (0.033) are not dissimilar from “organization innovations” (0.000), which are different from “process innovations” (0.104) and “marketing innovations (0.079) – with and without distribution innovations (0.060)”, which in turn are similar. That is, in this particular application “process and marketing innovations” exert a higher impact on market value than “product/service and organization innovations”: process innovations like the new “nhue restaurants” (e.g., NH Hotels, March 3, 2003) and organization innovation such as “variable salaries subject to share price variations” (e.g., NH Hotels, April 4, 2007 and Sol Meliá, June 6, 2004) might entail extra costs that might be regarded by investors as high. Certainly, “loyalty programs” such as the issue of loyalty cards with advantages for the clients like getting in earlier or staying later than normal guests, or allowing them to speed up the check-in process (e.g., NH Hotels, October 10, 2004) within marketing innovations do not require (in relative terms, of course) such high investment, while an increase in sales is expected. Note, however, that a company’s “energy commitments” (e.g., Sol Meliá, May 6, 2003 and April 7, 2008) within process innovations should parallel “product” and “organization” innovations in terms of costs; that is, high costs should be expected and therefore not-so-high returns should be obtained. Nevertheless, it is important to remember that the potential increment in sales should also be taken into account, especially for the specific news items observed that are related to environmental issues. Note that there is a green trend today (Chou et al., 2012; Han et al., 2011; Han and Kim, 2010; Kang et al., 2012; Pizam, 2009; Rahman et al., 2012) and an environmentally friendly wind blowing all over the business realm in the framework of social corporate responsibility that might lead investors to perceive this investment as less risky; in fact, consumers tend to favor socially responsible firms (Bhattacharya and Sen, 2003) and, when it comes to pro-environmental actions, positive relationships have been found between these green investments and hotel performance (García and Armas, 2007). In this regard, for these particular news types, the prospect of future sales might compensate the high costs implied, in line with the net benefit derived from implementing new energy systems evidenced by González and León (2001). In any case, the important result from this posterior analysis revolves around the fact that not all innovations are equal, and neither are their implications. Each innovation should be considered individually by managers, both between and within categories.

5. Conclusions

This article analyzes the effect of innovation on hotel market value. The results show that innovations are perceived to have a positive impact on the future sales of the company (note that market value is a future-oriented measure of cash-flow). Specifically, in a four-day period (from day 0 to day +3), there is an increase in returns of 1.53%; what is more, 1.53% in four days is equivalent to annual returns of 300% (this annual measure would be compared with other investments’ internal rate of return or discounted cash-flow, which are usually presented through annualized figures to use equivalent measures).

Also, in an attempt to further explain these returns derived from innovations, the news items are categorized into the four traditional types: product, process, organization and marketing (plus distribution). “Process” and “marketing” (and “distribution”) innovations have a higher positive effect on the market value than “product” and “organization” innovations. This shows that each innovation needs to be treated differently and individually, not only between but within categories, on account of cost differences among innovations.

5.1. Implications

Beyond the specific results of the empirical application, the study has important implications, both academic and managerial. Regarding academic implications, the finding that a hotel’s market value varies when the prospect of innovation activities is announced indicates that this measure can be regarded as appropriate to analyze this type of investment. This fact, along with the outcome that these variations in hotel market value are contingent upon the type of innovation, suggests that, when a comprehensive examination is pursued by the analyst, different types of innovation and distinct kinds of measurements should be employed. While different innovation types are expected to lead to different results, the use of several performance measures might allow the researcher to find hidden effects that, otherwise, would not be easy to uncover. Note that using distinct performance measures implies looking at the company from different perspectives; perspectives that represent facets that might be worth looking into.

As for managerial implications, the use of market value facilitates the analysis of the effect of innovation on performance by estimating unbiased market predictions on future profits. This technique employs a forward-looking firm performance measure that overcomes all the difficulties of the traditionally used backward-looking firm profitability, i.e., accounting measures. Specifically, once the innovation is announced, managers can observe the evolution of share prices to determine how valuable the news is perceived to be by the shareholders. If the shareholders’ perceptions of it are not as good as the managers would have expected, they may want to see whether this is due to a lack of information (or even to misinformation). If this were the case, a new flow of information should be released, in order to clarify the hotel’s innovation. Also, finding that innovation has a positive impact on firm market value means that the market considers that an innovative company is a healthy one. Therefore, any tourism company introducing innovations, no matter whether they are internal or external, should show that it is innovating all the time, by releasing news through a well-executed public relations system.

5.2. Limitation

Even though the process followed to collect the innovation news announcements in the hotel industry guarantees that, a priori, all of them must have been detected, the resulting sample size is a clear limitation; not so much because it affects its ability to capture potential reactions in share prices, but because it does not allow the inclusion of a larger number of potential explanatory variables that could shed further light on the innovation-related determinants of hotel market value.

5.3. Future research

For further research, several lines can be followed in order to provide a more comprehensive view of the relationship between innovation and market value in the hotel industry:

1. The paper uses the Schumpeterian classification to identify differentiated effects in innovation types; nevertheless, the use of other taxonomies would offer a broader view in terms of academic perspectives (as it would permit the identification of the best explanatory classification) as well as in terms of management perspectives (as it would show decision-makers the best innovation types according to the taxonomy used).
2. A larger sample would permit the use of factors related to a hotel’s characteristics; for example, the same innovation might have different effects on hotel performance depending on its category (e.g., number of stars).
3. The analysis of the effect of innovation on distinct tourism-related industries would show whether the same type of innovation has a differentiated influence (hotels, travel agencies, airlines, etc.).
4. The use of specific information on each innovation, especially in terms of costs incurred in the investment could shed more light on the specificities of every initiative; that is, knowing the cost invested in an innovation could determine how costly (per unit) the variations in market value are.
5. Risk analysis. Some innovation decisions are particularly relevant as sometimes they can imply enormous investments; this fact, together with the large amount of fixed costs generally involved in the hotel industry, makes them strongly revenue-dependent, which might lead to profit instability. Consequently, it would be critical to examine the effect of innovation on the risk of a hotel’s market value (measured through its volatility, for example).
6. There is a social trend today that favors corporate social responsibility (CSR) actions, so it would be interesting to see whether innovation oriented to enhance a hotel’s CSR exerts an incremental effect on performance. That is, as the CSR literature shows that these activities have a positive impact on market value and this article has shown that innovations also have a positive effect on market value, it would be worthwhile to analyze whether a greater effect exists when both activities – CSR and innovation – are linked together (e.g., the announcement of an innovation that allows a more efficient use of solar panels in hotels).
7. Recent literature has proven sequential interdependency between radical and incremental innovations (Martínez-Ros and Orfila-Sintes, 2009). It would be relevant to test the effect of this sequential interdependency on market value, as it would allow managers to determine the best innovation decisions (and their sequence) to optimize the firm’s market value.
8. As market value has been shown to reflect innovation announcements, it is possible to analyze the effect of innovation-based competitive reactions on the firm. In other words, as market value captures the hotel’s innovation strategy, it could be expected that it will reflect competitors’ innovation strategies too. It would facilitate a rivalry analysis between actions and reactions based on innovation strategies.
9. Innovation is supposed to enhance customer satisfaction, and it should be reflected in the “opinion polls” that are shown in most hotels’ web pages these days. On the one hand, the value
or ranking obtained in these polls can be used as an alternative measure of innovation effectiveness; and on the other, correlation analyses between the value/ranking obtained through these perceptions and a hotel's market value would show whether variations in market value are materialized in real terms too.

(10) With the advent of new technologies, other measurements of innovation impact can be used. If “twitter” were treated as a market where information is exchanged, and the number of “tweets” were considered as a measure of repercussion (or hype), it could be interesting to observe the expectations generated by an innovation announcement on a specific day. Paralleling the method employed in this article, it would imply observing whether the amount of “exchanged information” (tweets) derived from a firm’s release of news on a given day is abnormally superior to the quantity of “exchanged information” in a normal day, and whether and how many good things are said.
